

Introduction of Applied Cryptography

Chun-Jen (James) Chung

Arizona State University

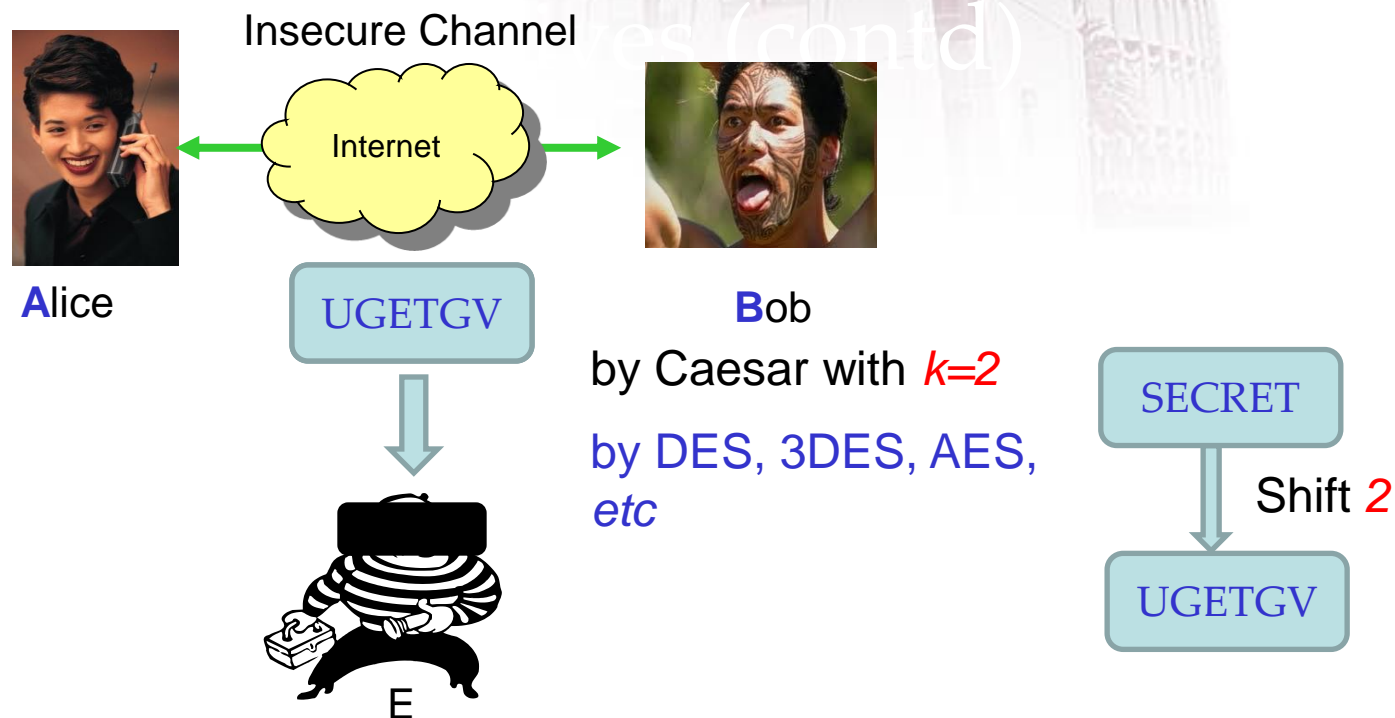

Outline

- Security and cryptography concepts
- Classical Encryption Techniques

Concepts

Q: Why do we need cryptography for systems and/or networks?

An example

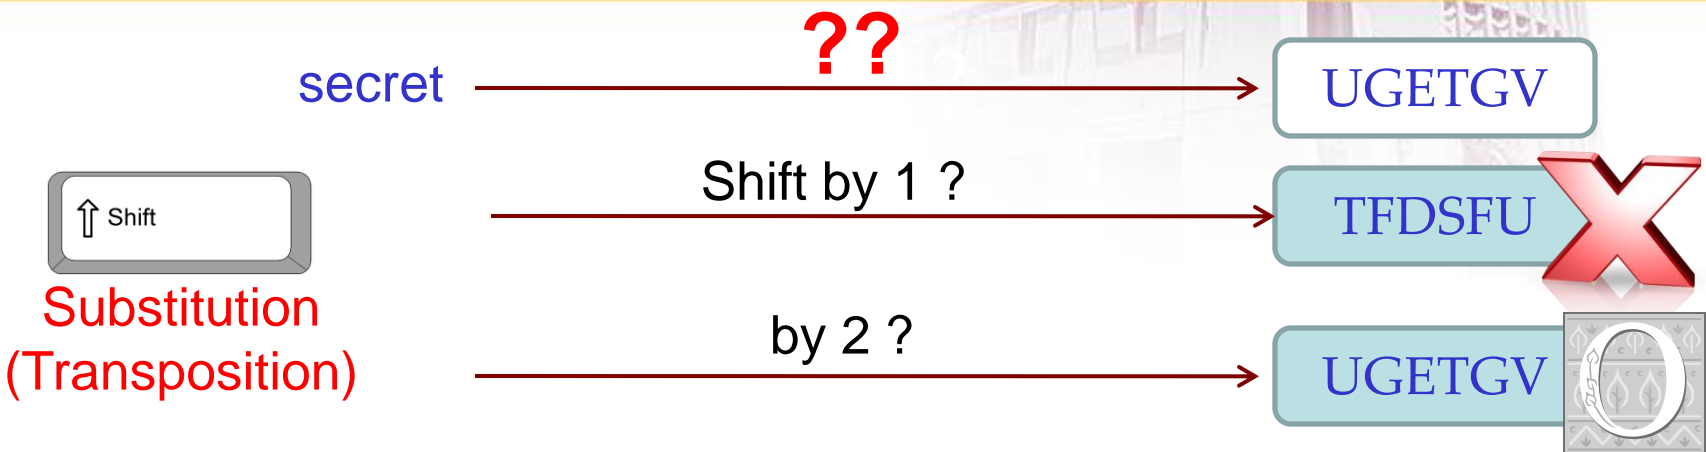

The data has not been viewed by a 3rd party

Confidentiality

Encryption

Confidentiality: the protection of transmitted data from passive attacks (release of message contents and traffic analysis)

Caesar cipher

CAESAR

key = 2

We will revisit this later

Confidentiality: Concealment of information or resources.

Use HMAC(Hashed message authentication code), such as HMAC-MD5, HMAC-SHA1

Alice

Bob

Wire transfer \$ to E

Inputs (e.g., msgs)

Fixed-size output

The data has not been modified in transit

Integrity

Cryptographic Hash func.

Integrity: the assurance that data received are exactly as sent by an authorized entity (i.e., contain no modification, insertion, deletion, or replay)

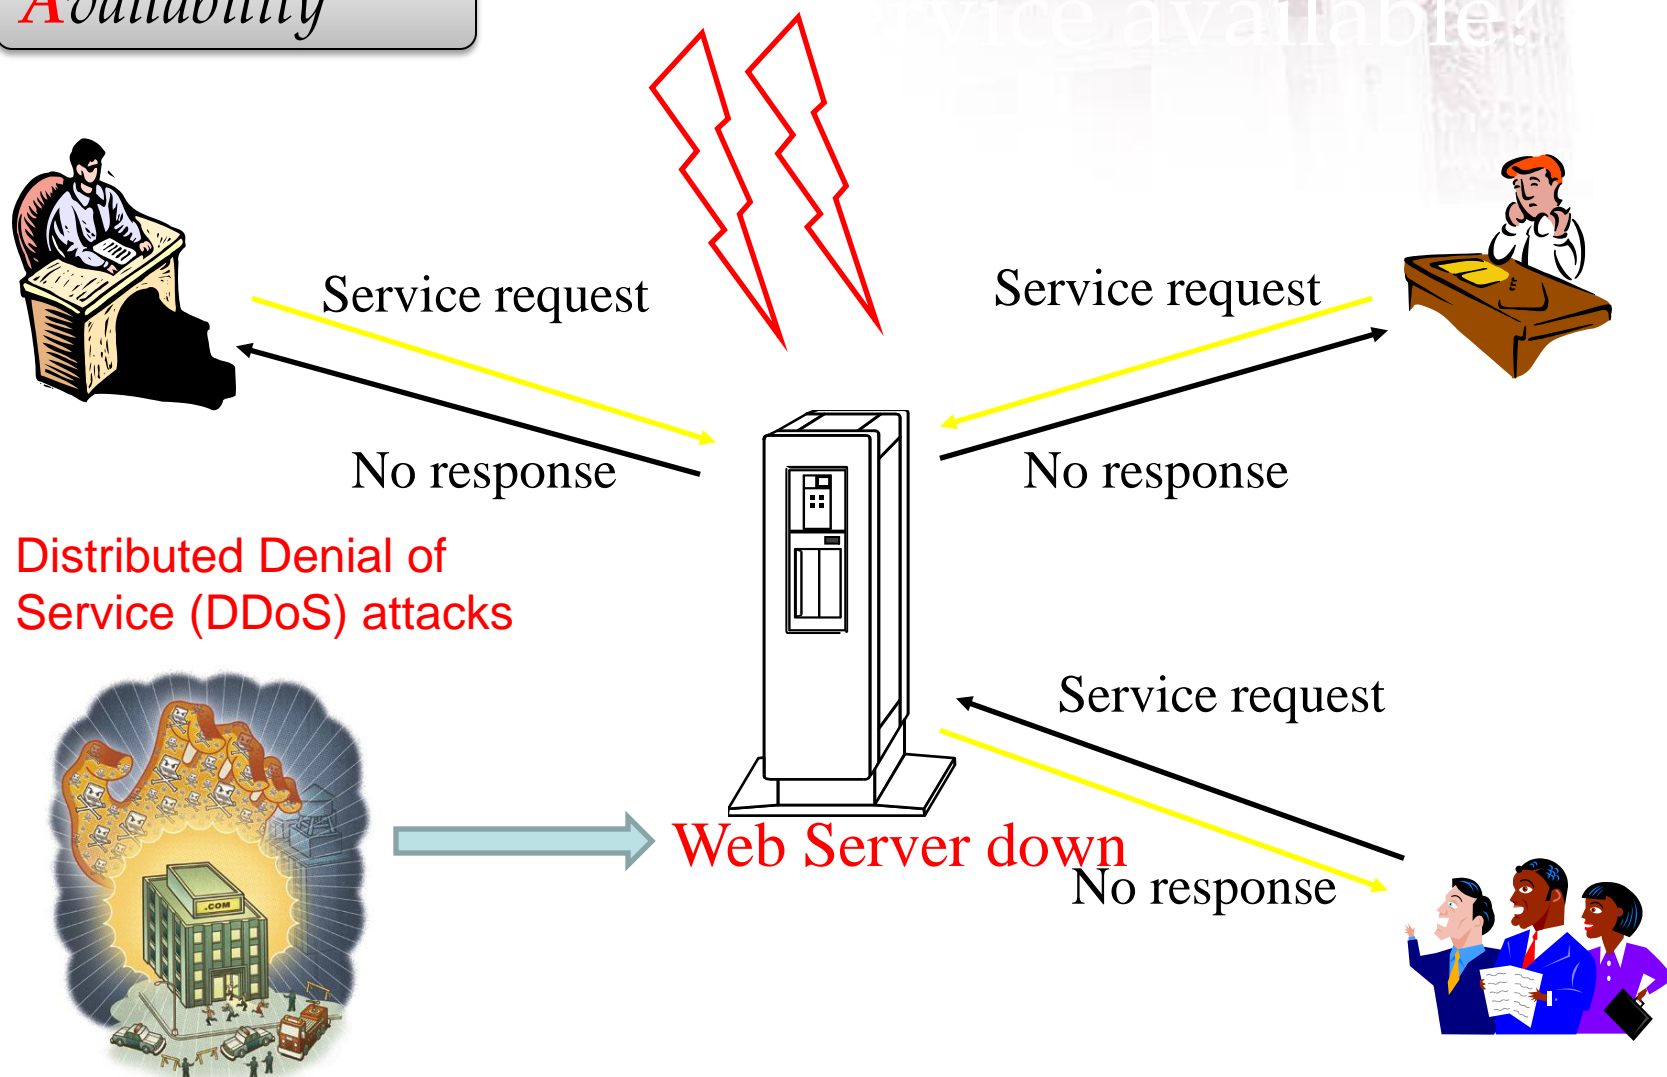

Distributed Denial of Service (DDoS) attacks

For any information system to serve its purpose, the information must be **available** when it is needed

Aailability

Availability

Alice

Bob

Cryptography

The data can not be viewed by a 3rd party

Confidentiality

Encryption

The data has not been modified in transit

Integrity

Hash func.

The data must be **available** when it is needed

Availability

Authentication
Non-repudiation

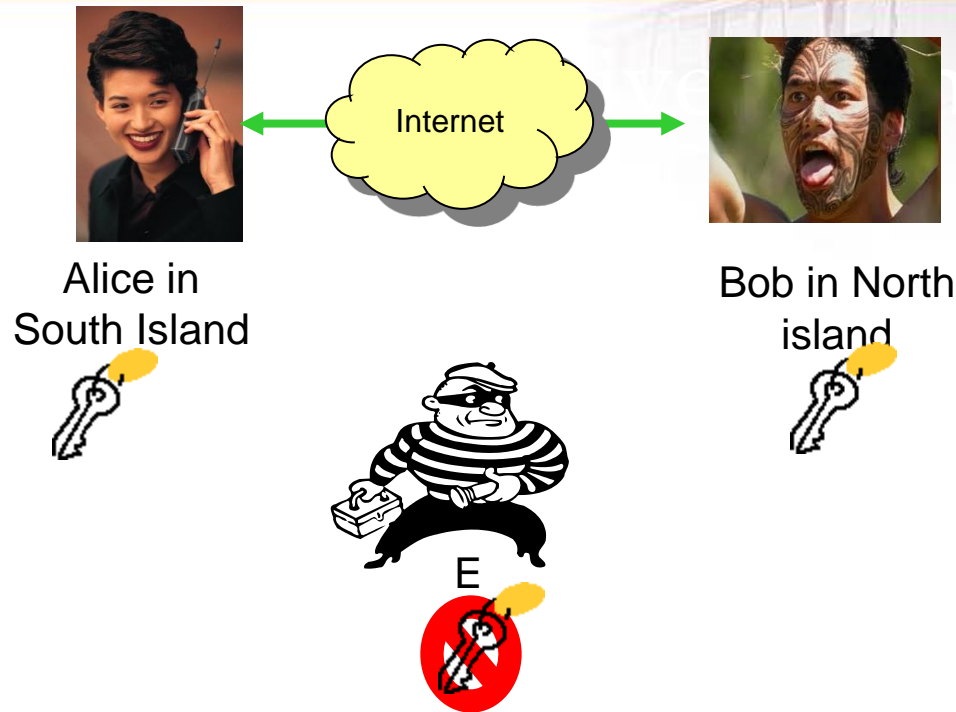

Encryption

Message
Authentication
code (MAC)

Hash func.

CSE468/598 Computer Network Security

The claimed sender is the true sender

Authentication

Encryption

Message
Authentication
code (MAC)

Hash func.

Authentication : the assurance that the communicating entity is the one that it claims to be.

Authentication: identification + verification

Who sent this message??

Authentication

= Origin *I*ntegrity

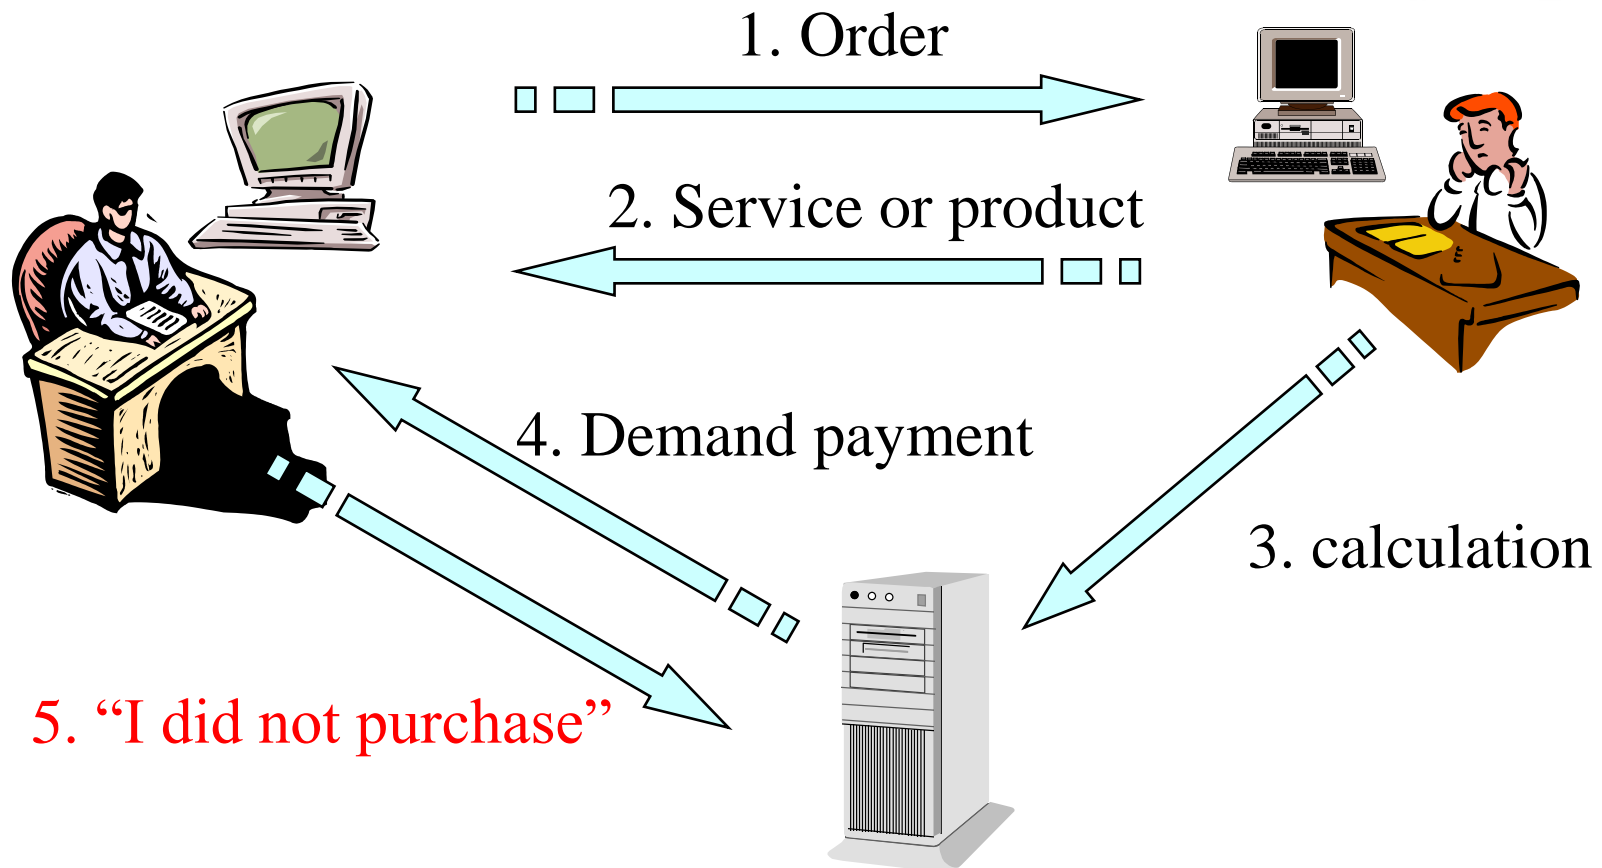

or

= Origin *I*ntegrity + Data *I*ntegrity

Non repudiation

Provides protections against *denial* by one of the entities involved in a communication of having participated in all or part of the communication

Security objectives summary

- Confidentiality
 - Prevent/detect/deter improper *disclosure* of information
- Integrity
 - Prevent/detect/deter improper *modification* of information
 - Authentication=Origin Integrity (or with Data Integrity)
- Availability
 - Prevent/detect/deter improper *denial of access to services* provided by the system
- These objectives have different specific interpretations in **different contexts**

Security mechanisms

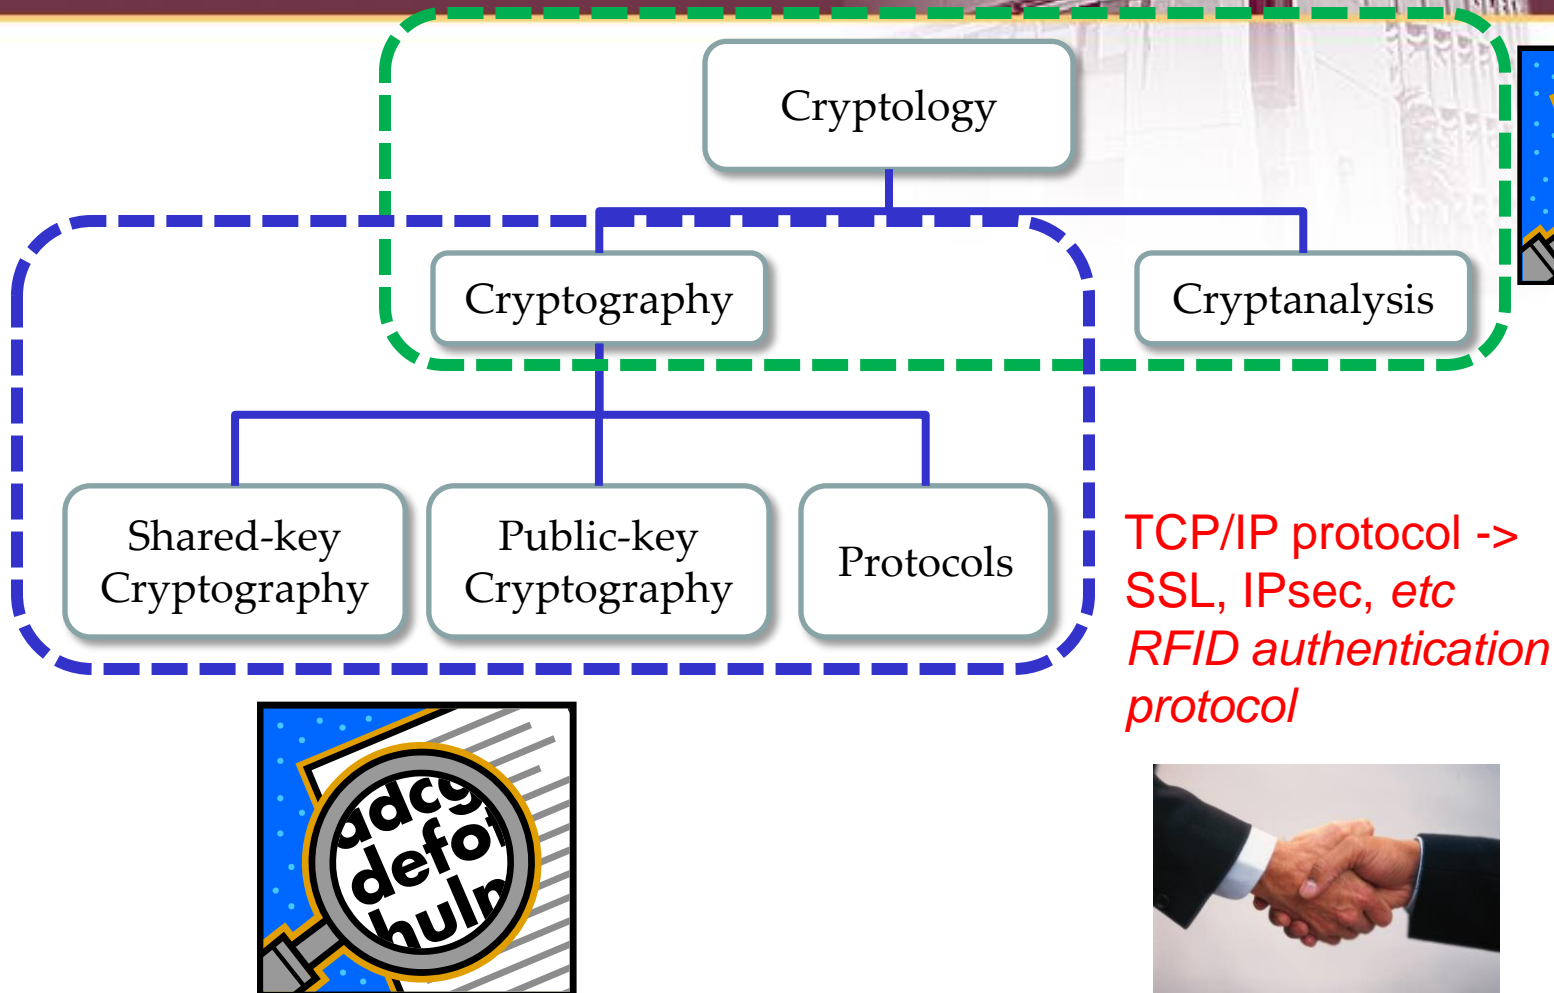

- In general, three types
 - Prevention
 - Example: access control (e.g., firewall)
 - Detection
 - Example: Auditing and intrusion detection (e.g., IDS, forensics)
 - Tolerance
 - Example: intrusion tolerance (e.g., ITS)

Cryptography underlies (almost) all security mechanisms

Introduction to Cryptography

Classical Encryption

Computationally secure vs. information-theoretically secure

Cryptology: Cryptography + Cryptanalysis

■ Cryptology

- study of mathematical, linguistic, and other coding patterns and histories
- An umbrella term for cryptography and cryptanalysis
- **cryptologist**

■ Cryptography

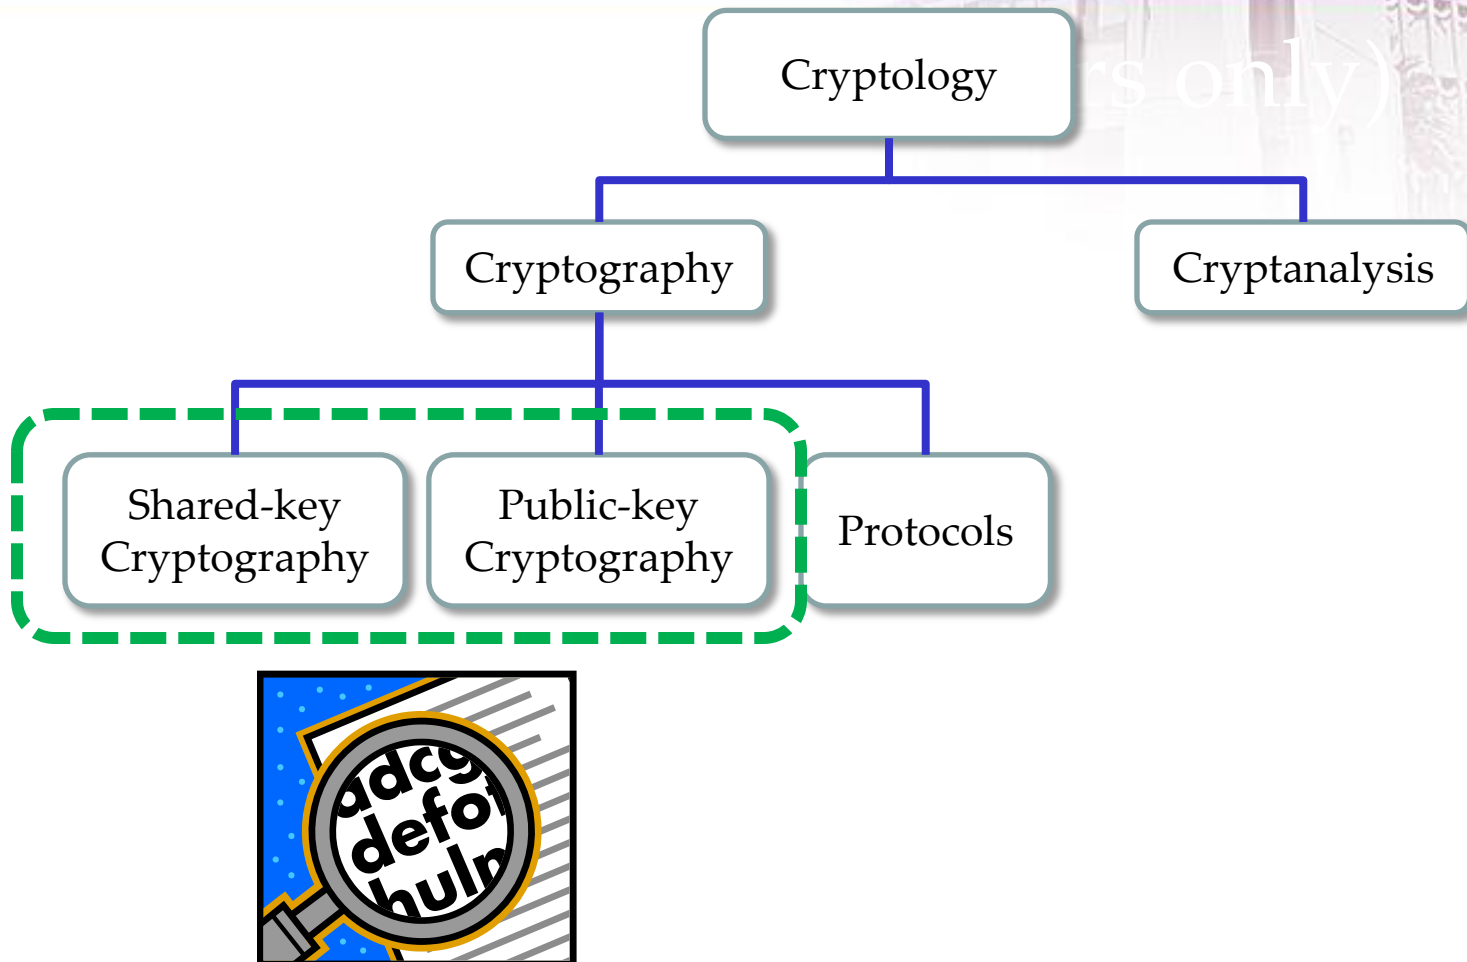

- study of *encryption* principles/methods,
- **cryptographer**

■ Cryptanalysis (codebreaking)

- the study of principles/methods of *deciphering* ciphertext without knowing key
- **cryptanalyst**

**conventional,
secret-key,
single key**

64 bits, 128 bits,
etc

Encryption
algorithms

Symmetric key

Asymmetric key

Block

Stream

1 bit (or 1 byte)

Later...

Feistel

SPN

etc

random

Pseudo
random

e.g., DES,
Triple-DES
SEED,
Blowfish

e.g., AES

- Block ciphers take a number of bits and encrypt them as a single unit, padding the plaintext so that it is a multiple of the block size.
- Stream ciphers encrypt the digits (typically bytes) of a message one at a time.

Symmetric
Encryption
algorithm

Symmetric
key

Caesar with $k=1$

Caesar with $k=1$

Attack(s)

love

Sender

love

Encryption
algorithm

MPWF

Decryption
algorithm

love

receiver

public key

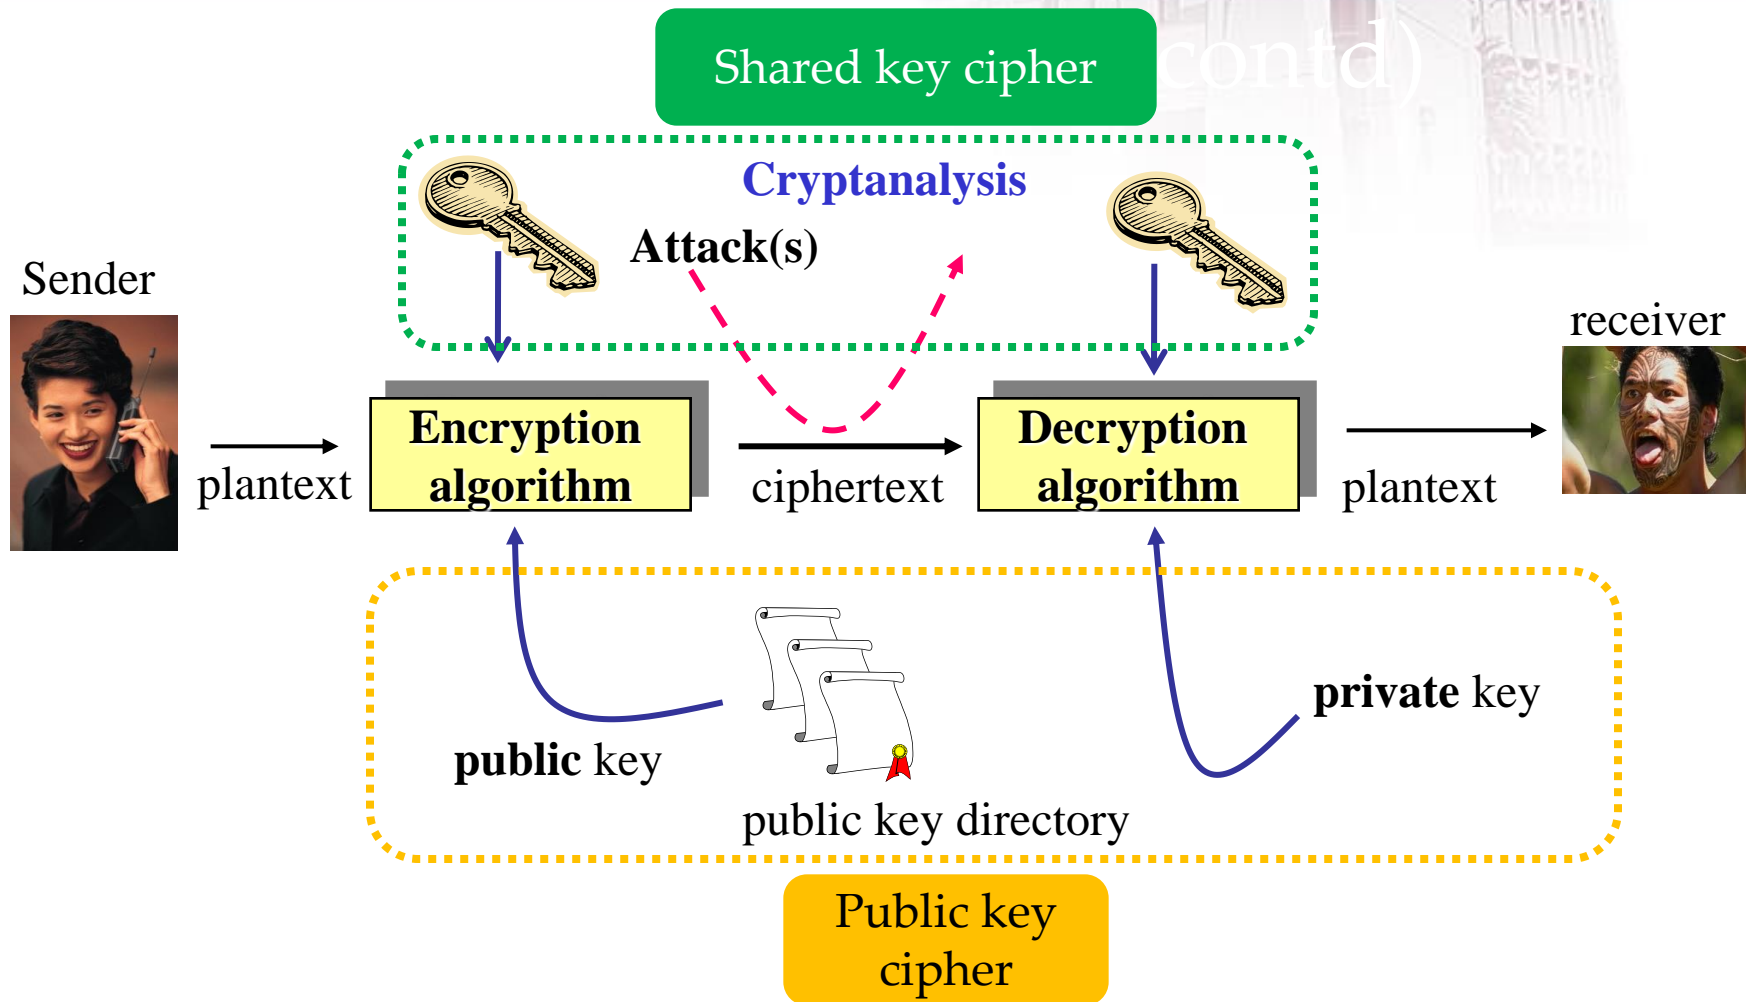

public key directory

private key

Asymmetric
key

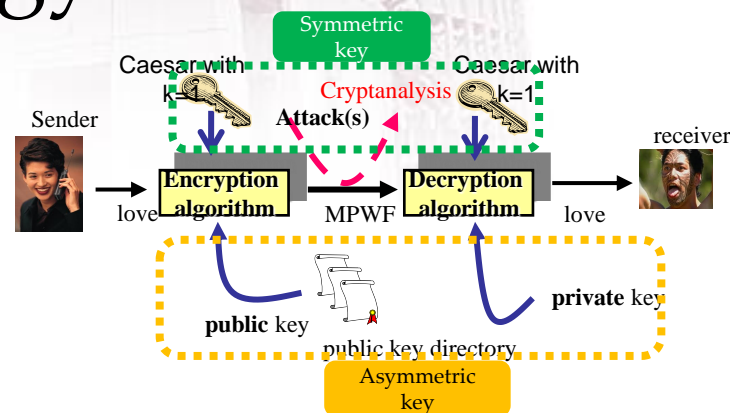

Later, RSA

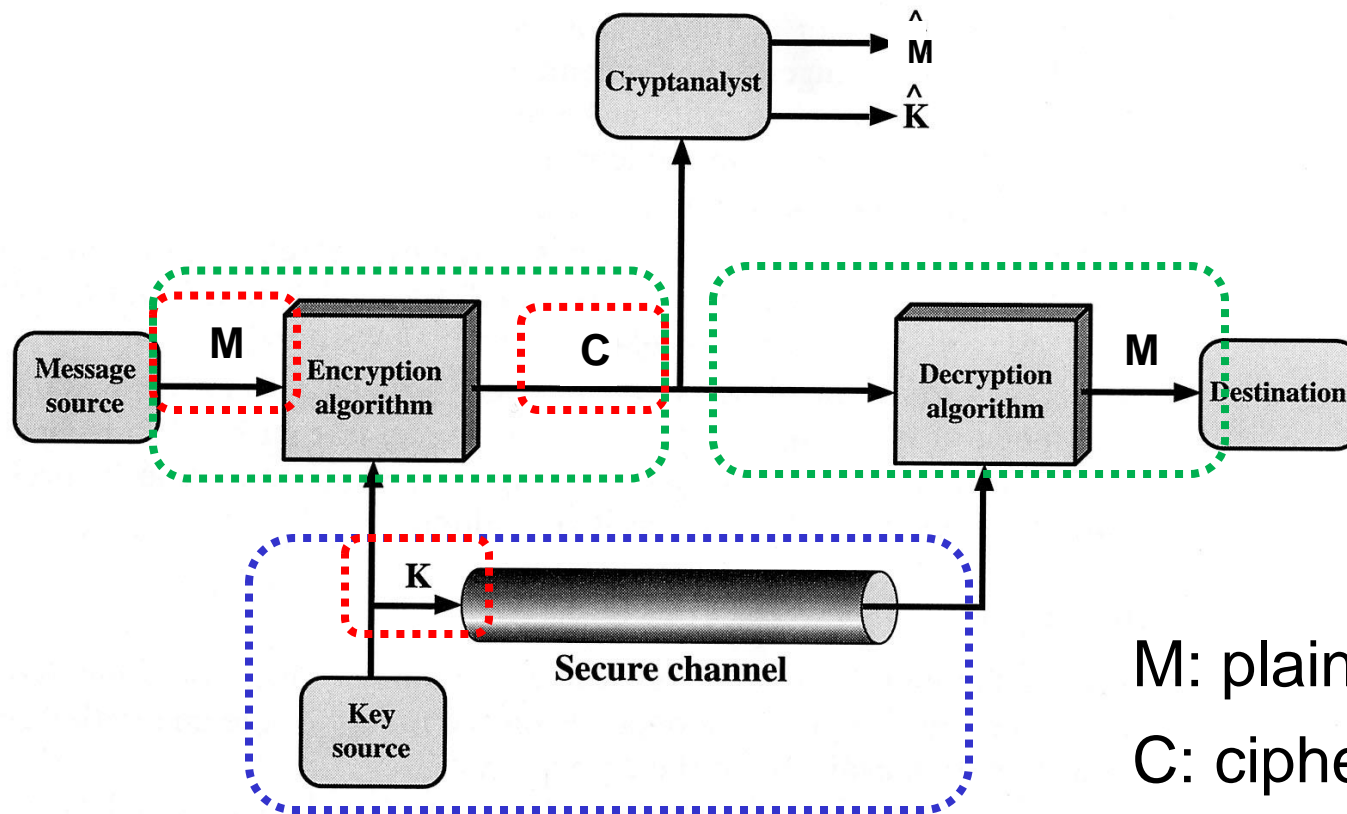

Basic Terminology

- **Cryptosystem:**
 - A system includes 3 algorithms:
key generation + Encryption + Decryption
- **Plaintext (M):**
 - the original message, e.g., love
- **Ciphertext (C):**
 - the coded (or encrypted) message, e.g., MPWF
- **Cipher** (Encryption/Decryption algorithm):
 - algorithm for transforming from plaintext (ciphertext) to ciphertext (plaintext), e.g., Caesar, DES, AES.
- **Key(s):**
 - info. used in cipher known only to sender/receiver in symmetric cipher.
- **Encrypt (encipher): $E(M)$**
 - converting plaintext to ciphertext; e.g., love \rightarrow MPWF
- **Decrypt (decipher): $D(C)$**
 - recovering ciphertext from plaintext; e.g., MPWF \rightarrow love

A symmetric key based Cryptosystem

This (key exchange/
distribution) will be
covered later

M : plaintext

C : ciphertext

K : key

E : encrypt $C = E_K(M)$

D : decrypt $M = D_K(C)$

Notations in a Cryptosystem

Symmetric

M: plaintext

C: ciphertext

K: key

E: encrypt $C = E_K(M)$

D: decrypt $M = D_K(C)$

Asymmetric

K_e : encryption key

K_d : decryption key

E: encrypt $C = E(M, K_e)$

D: decrypt $M = D(C, K_d)$

$\langle M \rangle_K$ indicates that "M" is encrypted with the key "K".

$\langle M1 | M2 \rangle_K$ indicates that "M1" and "M2" are encrypted with the key "K", Where $M1 | M2$ (or $M1 || M2$) is the concatenation of M1 with M2.

Principle of ciphers

- Use both **substitution** and **transposition**

- Proved by C. E. Shannon
- Using information theory in 1945
- **Product** ciphers
 - combines two or more transformations in a manner intending that the resulting cipher is more secure.

- Formulate the principles of “**confusion**” (standing for **substitution**) and “**diffusion**” (standing for **transposition**)

diffusion (transposition/permutation)

Spread the information from single plaintext letters over the entire ciphertext, making the plaintext randomly distributed in the cyphertext.

confusion
(substitution)

Make relationship between ciphertext and key as complex as possible, and make it harder to find the key

■ Substitution

- Change the character(s)
- Plaintext: come here at once
- Ciphertext:

■ Transposition (Permutation)

- Change the order of character
- Plaintext: come here at once

- Ciphertext: ocemehert a noec

Classical (Historical) ciphers

- **Substitution** ciphers

- Monoalphabetic

- The same plaintext letters are always replaced by the same ciphertext letters

- Polyalphabetic

- using multiple substitution alphabets

- Transposition ciphers

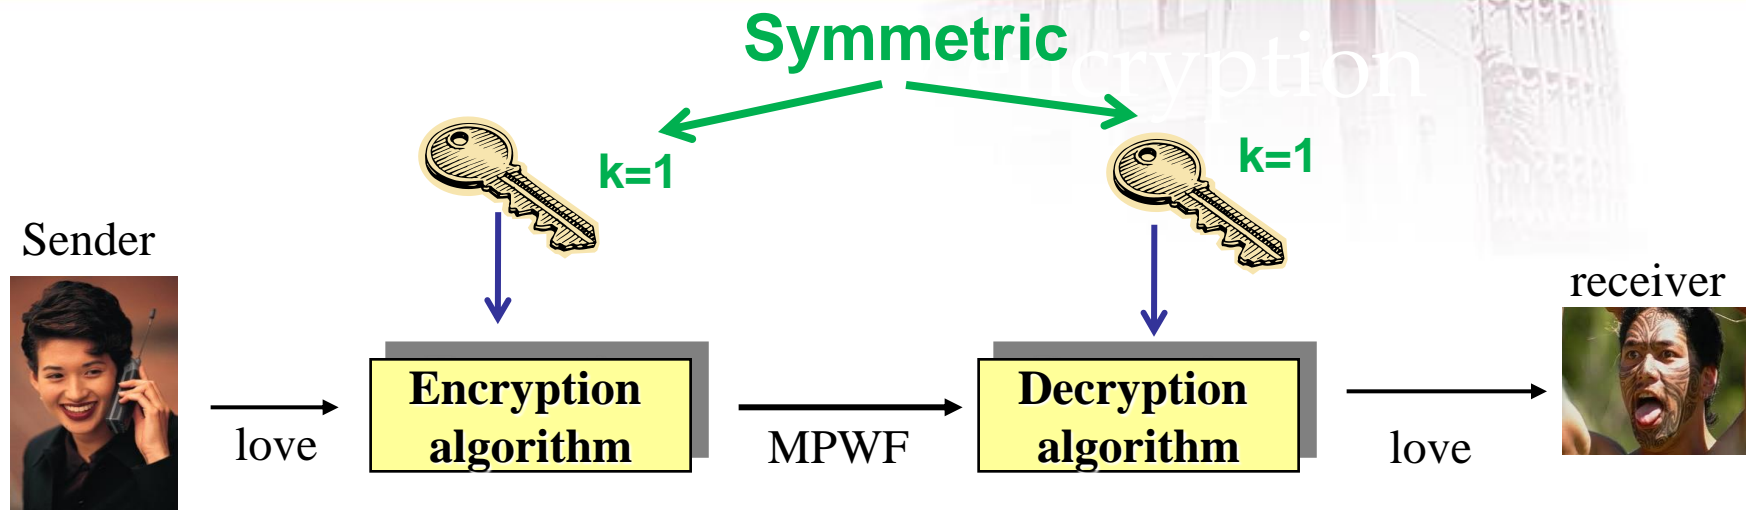

Caesar Cipher

- earliest known **substitution** cipher
 - Also known as shift cipher
- named after Julius Caesar
 - who used it in his private correspondence
- replaces each letter by the **i**th letter on

key = i

Q: If key (k) is 5? What will be the ciphertext of the plaintext "love"?

A: QT**A**J 

$$C \equiv E(M) \equiv M + k \pmod{26}$$

a **modulo** n (abbreviated as $a \pmod n$)

Mod. operation practice using a clock

- What is this?
 - An analog clock

Mod. operation practice

- Q: if we move the hour[short] hand by 6 hours?
consider it's a 12-hour clock

- 13? No.

- It indicates...

$$7+6 \bmod 12 \equiv 1$$

Or $7+6 \equiv 1 \pmod{12}$

Mod. operation practice

- When the hour[short] hand points out 7,
- how can we make it indicates 0, not using a negative number?

Not negative number: (-7)

$$(7 + \square) \bmod 12 = 0$$

- It is 5.
- **Q ? (4-6) mod 12?**

New clock ??

mathematically give each letter a number

letter	a	b	c	d	e	...	w	x	y	z
number	0	1	2	3	4	...	22	23	24	25

New clock

letters

a	b	c	d	e	...	w	x	y	z
0	1	2	3	4	...	22	23	24	25

Ex.1) key=3, E(c) ?

Ex.2) key=3, E(x)?

$$\begin{aligned}
 \text{Sol} &\equiv c + k \bmod 26 \\
 &\equiv 2 + 3 \bmod 26 \\
 &\equiv 5 \rightarrow F
 \end{aligned}$$

$$\begin{aligned}
 \text{Sol} &\equiv x + k \bmod 26 \\
 &\equiv 23 + 3 \bmod 26 \\
 &\equiv 26 \bmod 26 \equiv 0 \rightarrow A
 \end{aligned}$$

Q) key=3, E(y) ?

$$\begin{aligned}
 &\equiv 24 + 3 \bmod 26 \\
 &\equiv 27 \bmod 26 \equiv 1 \rightarrow B
 \end{aligned}$$

$$P \equiv D(C) \equiv (n-k) \bmod 26$$

Ex.3) key=3, D(F)?

Sol.) $(5-3) \bmod 26 \equiv 2 \rightarrow c$

Ex.4) key=3, D(A) ?

Sol.) $(0-3) \bmod 26 \equiv (-3) \bmod 26 \equiv 23 \rightarrow x$

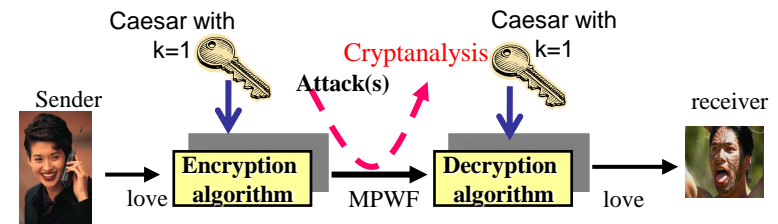

We will use this *mod* operation again when we learn the principle of **RSA** (most well-known public key encryption algorithm)

RSA (Ron **R**ivest, Adi **S**hamir and Leonard **A**dleman)

One more exercise ?

- Cipher (Caesar) is **known**
- Key is **hidden**
- **Q: What is then the plaintext for the following ciphertext?**

SRHECP
uofcan

- given ciphertext, just try all shifts of letters (**k=1, 2, 3, ...**)
- You did break the cipher using a brute-force attack!

Q: possible key size?

Caesar cipher

- Why Caesar cipher is too weak?
 - Possible key size is? 25

$$P \equiv D(C) \equiv (n-k) \bmod 26$$

25 keys

plaintext

Caesar cipher

break ciphertext "GCUA VQ DTGCM"

Answer : “easy to break”

Q: any ideas to improve this cipher?

A: use a Mono alphabetic Cipher which uses
an arbitrary substitution

We could shuffle (jumble) the letters **arbitrarily**;
each plaintext letter maps to a different random
ciphertext letter

Mono alphabetic Cipher

1) Use a key phrase (or keyword): e.g., ASINTOR.

a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t	u	v	w	x	y	z
A	S	I	N	T	O	R	U	V	W	X	Y	Z	B	C	D	E	F	G	H	J	K	L	M	N	P

2) Use other alphabet after 'R' except them used in the key phrase

3) Use remaining alphabets in the alphabetical order

Q: how many cases?

A: $26! = 26 \times 25 \times 24 \dots \times 2 \times 1 \approx 4 \times 10^{26}$

Q: Can we perform a cryptanalysis?

Mono alphabetic Cipher

The most common letters in English are ..

1. E
2. T
3. A
4. O
5. I
6. N
7. S
8. H
9. R

An example

- Ciphertext using Mono alphabetic Cipher

SLAAP UNAOL NVVKZ ABMMP UDOPS LRLLW PUNAO LIHKZ
ABMMV BAPZA OLJYP APJHS WYVIS LTAOH AHUFJ VTWBA
LYMPY LDHSS ULLKZ AVZVS CLPAO HZAVH JAHZN HALRL
LWLYP AOHZA VMPNB YLVBA DOPJO IPAZH YLOHY TMBSH
UKKLU FAOLT LUAYF PAOHZ AVKVA OPZDP AOVBA BUYLH
ZVUHI SFKLS HFPUN AYHMM PJ

- Frequency computation result

A: 29, B: 9, C: 1, D: 4, E: 0, F: 5, G: 0, H: 18, I: 4, J: 6,
K: 7, **L: 24**, M: 9, N: 6, O: 14, P: 18, Q: 0, R: 2, S: 10, T: 4,
U: 11, V: 14, W: 4, X: 0, Y: 11, Z: 12

1. E
2. T
3. A
...

- **Q: Strong candidate** key(s)?

- 'E' -> 'A' (22)
- 'E' -> 'L' (7)

- Q: Can we hide the frequency of alphabet?
- Any ideas?
 - Using a series of different Caesar ciphers in sequence with different shift values.

- It

w & s => g
i & e => b

Polygram Substitution
(polyalphabetic substitution.)

Using Vigenère cipher, E can be enciphered as different ciphertext letters at different points in the message, thus defeating simple frequency analysis

Vigenère cipher (cont'd)

- Cryptanalysis? The primary weakness of the Vigenère cipher is *the repeating nature of its key*.
- Kasiski test:
 - takes advantage of the fact that *repeated words* may, by chance, sometimes *be encrypted using the same key letters*, leading to *repeated groups in the ciphertext*.
 - For example, consider the following encryption using the keyword ABCD:
 - Plaintext: **CRYPTOISSHORTFORCRYPTOGRAPHY**
 - Key: **ABCDABCDABCDABCDABCDABCDABCD**
 - Ciphertext: **CSASTPKVSIQUTGQUCSASTPIUAQJB**
- There are more substitution ciphers though, we move on..

Classical (Historical) ciphers

- Substitution ciphers
 - Monoalphabetic
 - Polyalphabetic
- **Transposition** ciphers

Transposition (**permutation**) Cipher

- these hide the message by **rearranging** the letter order
- **without altering** the actual letters used
- can recognize these since have *the same frequency distribution* as the original text

Transposition Cipher

- Rail fence cipher (a.k.a., a zigzag cipher)
 - write message letters out downwards and diagonally over a number of rows or rails
 - then read off cipher row by row
 - Plaintext: meet me after the toga party

- ciphertext: MEMATRHTGPRYETEFETEOAAT

■ Rail fence cipher (cont'd)

- $P = p_1 p_2 p_3 \dots p_{16}$
- $C = p_1 p_5 p_9 p_{13} \dots p_{12} p_{16}$
- Ex. Plaintext:
 - LASTNITEWASHEAVENPLEASEMARRYME
- Ciphertext:
 - LTELAAEAERSWVARTAESYNSNEMIHPME
- Ciphertext
 - LEVSMTAAYIEERNHLRTSPASANMAWEEE

p_1	p_2	p_3	p_4
p_5	p_6	p_7	p_8
p_9	p_{10}	p_{11}	p_{12}
p_{13}	p_{14}	p_{15}	p_{16}

LASTNI
TEWASH
EAVENP
LEASEM
ARRYME

LTELAA
EAERSW
VARTAE
SYNSNE
MIHPME

This process is iterated, it is hard to guess the plaintext

Rounds in encryption

Plaintext

u n i v e r s i t y o f c a n t e r b u r y

key

4 5 3 2 8 7 6 1

Plaintext'

u	n	i	v	e	r	s	i
t	y	o	f	c	a	n	t
e	r	b	u	r	y	0	0

padding

Cipher
text

i	t	0	v	f	u	i	o	b	...
---	---	---	---	---	---	---	---	---	-----

Now think about ...

- Q: Why does the ciphers introduced so far not secure?
- A: because of language characteristics / **weak key size**
- Q: Any ideas to improve them (you already know the answer)?
- A: Use both substitution and transposition *together*

From classical to modern ciphers

- Consider using several ciphers in succession to make harder, but:
 - Two substitutions make a more complex substitution
 - Two transpositions make more complex transposition
 - But a substitution followed by a transposition makes a new much harder cipher
- Q: What is this type of ciphers called?
 - A: **product** ciphers
- This is the *bridge* from classical to modern ciphers

- Q: What is most well-known and widely used modern cipher(s)?
- A: **DES** (Data Encryption Standard),
AES (Advanced Encryption Standard),...
